July 16, 2014

# What is homology?

Homology is a rigorous mathematical method for defining and categorizing holes in a shape

Homological algebra: Linear algebra over rings

# Homology of the torus

$$\begin{aligned}H_0(\mathbb{T}) &= R \\H_1(\mathbb{T}) &= R \oplus R \\H_2(\mathbb{T}) &= R\end{aligned}$$

# Definition of homology

$$\cdots \longrightarrow C_{i+1} \xrightarrow{d_{i+1}} C_i \xrightarrow{d_i} C_{i-1} \longrightarrow \cdots$$

$$H_i = \ker(d_i) / \operatorname{im}(d_{i+1})$$

- $C_i$  is the  $i$ -dimensional “content”,
- $d_i$  maps the  $i$ -dimensional “content” on its boundary,
- $H_i$  is the  $i^{\text{th}}$ -homology group.

# The triangle

$$0 \xrightarrow[d_2]{0} \mathbb{Z}[ab, ac, bc] \xrightarrow[d_1]{\begin{pmatrix} -1 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & -1 & 1 \end{pmatrix}} \mathbb{Z}[a, b, c] \xrightarrow[d_0]{0} 0$$

$$H_0 = \ker(d_0)/\text{im}(d_1) = \mathbb{Z}[a, b, c]/\text{im}(d_1) \simeq \mathbb{Z}$$

$$H_1 = \ker(d_1)/\text{im}(d_2) \simeq \ker(d_1) \simeq \mathbb{Z}$$

# $\mathbb{Z}$ -homology vs. $\mathbb{F}_2$ -homology

For the Torus it does not matter if computations are done in  $\mathbb{Z}$  or  $\mathbb{F}_2$ :

	$\mathbb{Z}$	$\mathbb{F}_2$
$H_0(\mathbb{T})$	$\mathbb{Z}$	$\mathbb{F}_2$
$H_1(\mathbb{T})$	$\mathbb{Z} \oplus \mathbb{Z}$	$\mathbb{F}_2 \oplus \mathbb{F}_2$
$H_2(\mathbb{T})$	$\mathbb{Z}$	$\mathbb{F}_2$

This is not always true, e.g. Klein bottle.

# Klein bottle

Homology groups:

	$\mathbb{Z}$	$\mathbb{F}_2$
$H_0(\mathbb{K})$	$\mathbb{Z}$	$\mathbb{F}_2$
$H_1(\mathbb{K})$	$\mathbb{Z} \oplus \mathbb{Z}_2$	$\mathbb{F}_2 \oplus \mathbb{F}_2$
$H_2(\mathbb{K})$	$0$	$\mathbb{F}_2$

# $\mathbb{Z}$ -homology vs. $\mathbb{F}_2$ -homology

With  $\mathbb{F}_2$ -homology  $\mathbb{T}$  and  $\mathbb{K}$  are indistinguishable!

$\mathbb{Z}$ -homology is more informative.

Goal: Compute  $R$ -homology with Coq

# Definition of homology

$$\cdots \longrightarrow C_{i+1} \xrightarrow{d_{i+1}} C_i \xrightarrow{d_i} C_{i-1} \longrightarrow \cdots$$

$$H_i = \ker(d_i)/\operatorname{im}(d_{i+1})$$

Required features:

- **$R$ -modules**:  $C_i$ ,
- **morphisms** of  $R$ -modules:  $d_i$ ,
- **kernel** and image,
- quotient of a submodule by another.

# Finitely presented modules

We take an approach similar to the one in the SSReflect library where finite dimensional vector spaces are represented using matrices and all subspace operations are defined from Gaussian elimination

- Finite dimensional vector spaces  $\implies$  Finitely presented modules
- Gaussian elimination  $\implies$  Coherent and strongly discrete rings

# Finitely presented modules

An  $R$ -module is **finitely presented** if it can be represented by:

- a finite number of generators (e.g.  $e_0, e_1$ ),
- and relations between these (e.g.  $2e_1 = 0$ ).

That is, it can be represented by an exact sequence:

$$R^{m_1} \xrightarrow{M} R^{m_0} \longrightarrow \mathcal{M} \longrightarrow 0$$

# Finitely presented modules

The  $\mathbb{Z}$ -module  $\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$  is given by the presentation:

$$\mathbb{Z} \xrightarrow{\begin{pmatrix} 0 & 2 \end{pmatrix}} \mathbb{Z}^2 \longrightarrow \mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z} \longrightarrow 0$$

as if  $\mathbb{Z} \oplus \mathbb{Z}/2\mathbb{Z}$  is generated by  $(e_0, e_1)$  there is one relation, namely  $0e_0 + 2e_1 = 0$ .

# Coherent and strongly discrete rings

To conveniently represent morphisms and compute their kernel the underlying ring needs to be:

- Coherent: it is possible to compute generators of the kernel of any matrix
- Strongly discrete: membership in finitely generated ideals is decidable

# Coherent and strongly discrete rings

If  $R$  is both coherent and strongly discrete we can solve arbitrary systems  $XM = A$ , we write:

$$M \mid A \Leftrightarrow \exists X. XM = A$$

Examples: fields (Gaussian elimination),  $\mathbb{Z}$  (Smith normal form),  $k[x_1, \dots, x_n]$  (Gröbner bases)...

# Coherent and strongly discrete rings

This gives a means for testing if a matrix is zero modulo a set of relations:

$$\begin{aligned} & A \text{ is zero in the module } \mathcal{M} \\ \Leftrightarrow & \exists X, XM = A \\ \Leftrightarrow & M \mid A \end{aligned}$$

and we get a nice divisibility theory for matrices:

**Lemma**  $d \times m \times n \times k$  ( $M : {}^m M[R]_{(m,n)}$ )  
( $N \ K : {}^k M[R]_{(k,n)}$ ) :  
 $M \mid N \rightarrow M \mid K \rightarrow M \mid N + K.$

# Finitely presented modules: morphisms

A morphism between finitely presented  $R$ -modules is given by:

$$\begin{array}{ccccccc} R^{m_1} & \xrightarrow{M} & R^{m_0} & \longrightarrow & \mathcal{M} & \longrightarrow & 0 \\ \downarrow Y & & \downarrow X & & \downarrow \varphi & & \\ R^{n_1} & \xrightarrow{N} & R^{n_0} & \longrightarrow & \mathcal{N} & \longrightarrow & 0 \end{array}$$

In our setting  $\varphi$  may be represented by  $X$  and a proof that  $N \mid MX$

# Finitely presented modules: morphisms

```
Record fpmodule := FPModule {  
  nbrel : nat;  
  nbgen : nat;  
  pres : 'M[R]_(nbrel, nbgen)  
}.
```

```
Record morphism_of (M N : fpmodule) :=  
  Morphism { X : 'M[R]_(nbgen M, nbgen N);  
    _ : pres N %| pres M *m X }.
```

# Kernel modulo

To compute the kernel of a morphism we need to compute the kernel of a matrix **modulo** a set of relations.

$$\begin{aligned} XM = 0 \text{ in } \mathcal{N} &\Leftrightarrow \exists Y, XM + YN = 0 \\ &\Leftrightarrow \exists Y, (x \ y) \begin{pmatrix} M \\ N \end{pmatrix} = 0 \end{aligned}$$

Solving this amounts to computing  $\ker \begin{pmatrix} M \\ N \end{pmatrix}$

# Kernel of a morphism

The kernel of a morphism  $\varphi : \mathcal{M} \rightarrow \mathcal{N}$  is given by *two* things:

- 1 A finitely presented module  $\mathcal{K}$
- 2 An injection  $\ker(\varphi) : \mathcal{K} \rightarrow \mathcal{M}$

Both of these are computed by the “kernel modulo” operation

# Kernel of a morphism

$$\begin{array}{ccccccc} R^{m_1} & \xrightarrow{M} & R^{m_0} & \longrightarrow & \mathcal{M} & \longrightarrow & 0 \\ Y \downarrow & & \downarrow X & & \downarrow \varphi & & \\ R^{n_1} & \xrightarrow{N} & R^{n_0} & \longrightarrow & \mathcal{N} & \longrightarrow & 0 \end{array}$$

# Kernel of a morphism

$$\begin{array}{ccccccc} R^{k_1} & \xrightarrow{\ker_M(\ker_N(X))} & R^{k_0} & \longrightarrow & \mathcal{K} & \longrightarrow & 0 \\ \downarrow & & \downarrow \ker_N(X) & & \downarrow \ker(\varphi) & & \\ R^{m_1} & \xrightarrow{M} & R^{m_0} & \longrightarrow & \mathcal{M} & \longrightarrow & 0 \\ Y \downarrow & & \downarrow X & & \downarrow \varphi & & \\ R^{n_1} & \xrightarrow{N} & R^{n_0} & \longrightarrow & \mathcal{N} & \longrightarrow & 0 \end{array}$$

# Definition of homology in Coq

Using our formalization we can write:

```
Variables (M N P : fpmodule R)
  (phi : 'Mor(M, N)) (psi : 'Mor(N, P)).
```

```
Hypothesis mul_phi_psi : phi ** psi %= 0.
```

```
Definition homology := kernel psi %/ phi.
```

# Abelian categories

How do we know that our definitions are correct?

# Abelian categories

How do we know that our definitions are correct?

Abelian categories: Introduced by Grothendieck to describe categories suitable for developing homological algebra

Goal: Prove that our implementation of finitely presented modules form an abelian category

# Abelian categories

A category is **abelian** if:

- the hom-sets form abelian groups ( $+$ ,  $-$  and  $0$  for morphisms),
- it has (finite) sums and products,
- any morphism has a **kernel** and cokernel, and
- all **monomorphisms** and epimorphisms are **normal**.

# Addition of morphisms

Given

$$\begin{array}{ccccccc} R^{m_1} & \xrightarrow{M} & R^{m_0} & \longrightarrow & \mathcal{M} & \longrightarrow & 0 \\ \downarrow Y_1, Y_2 & & \downarrow X_1, X_2 & & \downarrow \varphi_1, \varphi_2 & & \\ R^{n_1} & \xrightarrow{N} & R^{n_0} & \longrightarrow & \mathcal{N} & \longrightarrow & 0 \end{array}$$

How do we form  $\varphi_1 + \varphi_2$ ?

# Addition of morphisms

Given

$$\begin{array}{ccccccc} R^{m_1} & \xrightarrow{M} & R^{m_0} & \longrightarrow & \mathcal{M} & \longrightarrow & 0 \\ \downarrow Y_1, Y_2 & & \downarrow X_1, X_2 & & \downarrow \varphi_1, \varphi_2 & & \\ R^{n_1} & \xrightarrow{N} & R^{n_0} & \longrightarrow & \mathcal{N} & \longrightarrow & 0 \end{array}$$

How do we form  $\varphi_1 + \varphi_2$ ?

Recall that  $N \mid MX_1$  and  $N \mid MX_2$ . So by the divisibility theory for matrices we get:  $N \mid M(X_1 + X_2)$

# Kernels of morphisms

A morphism  $\varphi : M \rightarrow N$  has a kernel  $\kappa : K \rightarrow M$  if  $\kappa\varphi = 0$  and for all  $\psi : L \rightarrow M$  with  $\psi\varphi = 0$  there exists  $\zeta : L \rightarrow K$  such that the following diagram commutes:

# Kernels of morphisms

**Definition** `is_kernel` (M N K : fpmodule R)  
(phi : 'Mor(M,N)) (k : 'Mor(K,M)) :=  
(k \*\* phi %= 0) \*  
`forall` L (psi : 'Mor(L,M)),  
reflect (exists Y, Y \*\* k %= psi)  
          (psi \*\* phi %= 0).

**Lemma** `kernelP` M N (phi : 'Mor(M,N)) :  
`is_kernel` phi (kernel phi).

# Monomorphisms are normal

As we can subtract morphisms we say that a morphism  $\varphi$  is **monomorphism** if whenever  $\psi\varphi = 0$  then  $\psi = 0$

```
Definition is_mono M N (phi : 'Mor(M,N)) :=  
  forall L (psi : 'Mor(L,M)),  
    psi ** phi %= 0 -> psi %= 0.
```

# Monomorphisms are normal

A monomorphism is **normal** if it is a kernel of its cokernel

**Lemma** `mono_ker M N (phi : 'Mono(M,N)) :`  
`is_kernel (coker phi) phi.`

Hence we get that the category of finitely presented modules over coherent strongly discrete rings is abelian

# Conclusions

- Finitely presented modules provides a nice setting for formalizing constructive module theory
- Kernel modulo and matrix division gives short and simple proofs
- Finitely presented modules is a good setting for developing constructive homological algebra

# Future work

- Develop the theory of abelian categories
- Formalize graded objects like graded modules and chain complexes
- More functors: resolutions, Hom, cohomology, Ext, Tor...
- Quotient by morphism equality
- Quotient by module isomorphism (requires SNF or HoTT)

# Thank you!
